High Temperature Resistance of Aviation Electronic Fiber Optic Spectrometer

Overview

In particular, fiber optic sensors, with their small footprint and electromagnetic immunity, represent a great opportunity in aerospace.

Key Takeaways

Aviation fiber optic spectrometers can reliably operate at temperatures up to 600°C with specialized high-temperature fibers and sensor packaging, while ultra-high temperature systems may tolerate up to 1000°C.Fiber Materials and Temperature Limits

The high-temperature resistance of fiber optic spectrometers in aviation primarily depends on the fiber material. Standard silica fibers are commonly used but typically withstand temperatures up to 600°C. For extreme aerospace environments, crystal fibers or fibers integrated with ultra-high temperature ceramic (UHTC) materials are employed, allowing operation in environments exceeding 1000°C . The choice of fiber material directly affects the maximum operational temperature, sensitivity, and long-term stability of the spectrometer.

Sensor Types and Principles

© 2026 ZITHA TECH SPECIALTY CABLES (Pty) Ltd - All rights reserved

High-temperature fiber optic spectrometers often use Fiber Bragg Grating (FBG) sensors, which reflect specific wavelengths of light that shift with temperature changes. Other types include interferometric sensors, fluorescence-based sensors, and distributed temperature sensors (DTS). These sensors are compact, immune to electromagnetic interference, and capable of multiplexing, making them suitable for aerospace applications where space and weight are critical .

Packaging and Structural Considerations

To enhance thermal resistance, FBG sensors are often tube-packaged, embedded, or surface-attached with specialized bonding techniques. Proper packaging ensures mechanical stability, protects the fiber from thermal expansion, and maintains measurement accuracy under high thermal loads . Multi-sensor interrogation systems using tunable lasers and optical switches allow simultaneous monitoring of temperature, strain, and pressure, which is essential for structural health monitoring (SHM) in aircraft .

Performance and Testing

Experimental studies have demonstrated that high-temperature FBG sensors maintain good sensitivity, resolution, repeatability, and dynamic range up to 600°C. For ultra-high temperature applications, such as monitoring UHTC components in aerospace structures, fiber optic systems are designed to withstand thermal loads up to 1000°C, although standard fibers cannot tolerate such extremes . The electro-optical interrogation systems are flexible, allowing adaptation for mechanical stress analysis alongside temperature monitoring.

Summary

In aviation applications, the high-temperature resistance of fiber optic spectrometers is determined by fiber material, sensor type, and packaging. Standard high-temperature FBG sensors operate reliably up to 600°C, while advanced systems using UHTC materials can tolerate temperatures approaching 1000°C. These systems provide precise, multiplexed, and EMI-immune measurements, making them ideal for structural health monitoring and extreme aerospace environments .
