How deep should the temporary distribution box be grounded

Overview

Safety should never be compromised, and all installations must adhere to the code, whether temporary or permanent.

Key Takeaways

Temporary distribution boxes should be grounded using rods driven sufficiently into the earth to achieve a low-resistance connection, typically ensuring a ground resistance of less than 25 ohms.Key Grounding Principles

Temporary grounding is essential to protect personnel and equipment when working on de-energized circuits or during maintenance. The grounding system must ensure that all phases and conductive parts are bonded together and connected to earth to prevent hazardous voltages in case of accidental energization (NFPA 70E 120.4(B)(7)), .

Ground Rod Installation
• Depth: While exact depth can vary depending on soil conditions, temporary ground rods are generally driven deep enough to achieve a reliable low-resistance connection, often several feet into the earth. The goal is to reach a resistance of less than 25 ohms for effective dissipation of fault currents .

• Multiple Rods: If a single rod does not achieve the required resistance, multiple rods connected with a continuous conductor should be installed to meet the resistance target .

• Placement: Rods should be installed near the distribution box or structure being grounded, ensuring that all conductive parts within reach of personnel are bonded to the grounding system .
Temporary Protective Grounding Setup
• Use a grounding cluster or jumper to connect each de-energized phase bus and the equipment grounding terminal bar to the ground rod or system .

• Ensure that the grounding system creates an equipotential zone, minimizing step and touch voltages for workers .

• Verify the grounding connection before starting work, and remove temporary grounds only after confirming the circuit is ready to be re-energized .
Practical Considerations
• Soil Conditions: Moist, conductive soil improves grounding effectiveness, while dry or rocky soil may require longer rods or additional rods.

• Material Quality: Use copper-bonded steel rods or equivalent high-quality materials to prevent corrosion and maintain low resistance over time .

• Testing: Always measure the ground resistance after installation to ensure compliance with safety standards. By following these guidelines, temporary distribution boxes can be safely grounded, protecting both personnel and equipment during maintenance or temporary power operations.
